# Recap

- Each Bird represents one possible solution (one tour)
- Each operation performed by a bird, alters its respective solutions

# Recap

# Recap

- Each action of a bird corresponds to a change of its own solution
- Each solution is valid
- The number of candidate solutions (or agents respectively) does not change (currently)

(1) Walk

(2) Fly

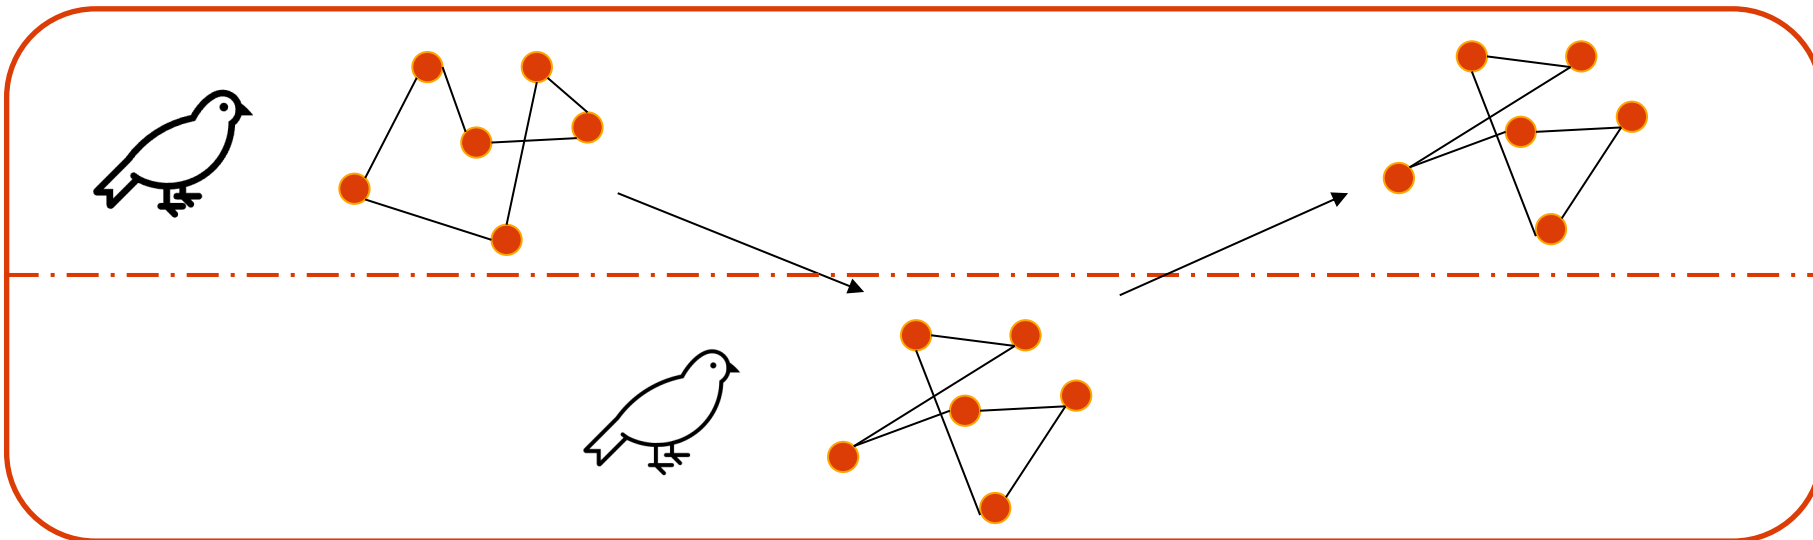

# Recap

## (3) Return

## (4) Join

# Methodology

- To benchmark our improvements, we select five feasible solutions from TSPLIB
  - Each problem has a different order of magnitude to account for the variety of different configurations possible
- Each problem is run 10x, to account for the randomness (50 test in total)
- We record the mean percentage error, and the mean time in seconds
- Problems: eil101, pa561, pr1002, u2156, pr2392

# Top-b Join

- Default behavior: If a big bird joins another, he chooses one randomly
- Contradicts the idea that birds tend to join others, if they found a good food source
  - Good food source translates to a good solution
- That is why we decide to allow a big bird to only join the top-b percent
  - Pick one of the top-b birds randomly
- Means ordering the birds by their tour length after each iteration/phase
  - Increases runtime due to sorting complexity

# Top-b Join

# 3-Opt

- When performing the walk-operation, so the local search, a bird uses 2-opt to search for a potential better solution
- Naturally, we also tested 3-opt as a more powerful alternative

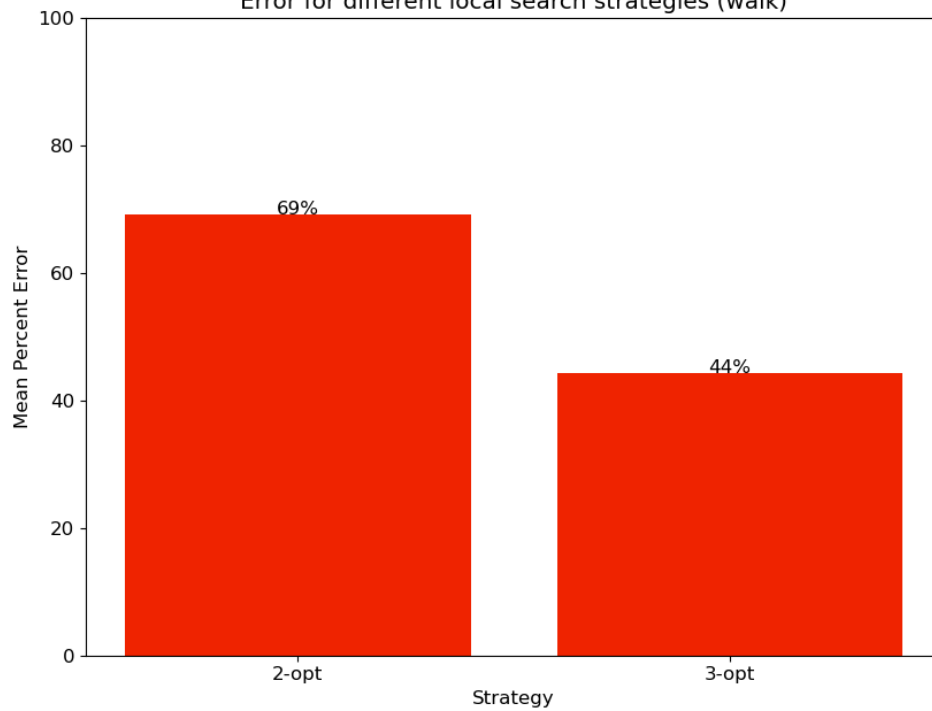

Source: Jingyan Sui, Shizhe Ding, Ruizhi Liu, Liming Xu, Dongbo Bu. Learning 3-opt heuristics for traveling salesman problem via deep reinforcement learning. Proceedings of The 13th Asian Conference on Machine Learning, PMLR 157:1301-1316, 2021.

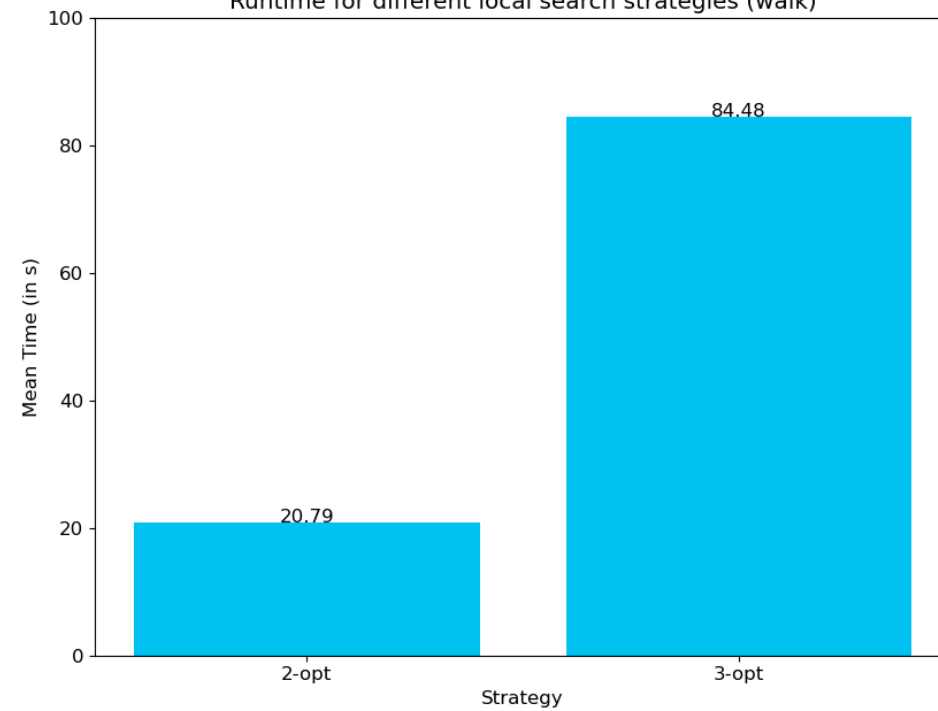

# 3-Opt

Error for different local search strategies (walk)

Runtime for different local search strategies (walk)

# Delegating Responsibility

- Seen before: 3-opt (+ sorting for top-b join) yield very high computation effort
- How can one make the algorithm faster while keeping the performance close to before?
- Answer: Allow only big/small birds to perform 3-opt, the other 2-opt
  - Both were tested, but big birds make more sense regarding their “superiority”

# Nearest-Neighbor Initialization

- Instead of starting with random tours, use a simple heuristic for initialization
- Nearest neighbor algorithm
  - Runtime:  $O(n^2)$
- Algorithm
  - Start with a random vertex, mark it as visited
  - Add the nearest neighbour of the current vertex, mark it as visited and make it the new current vertex
  - If all vertices are visited the tour is complete

# Early Stopping

- Algorithm shows very fast convergence behavior
  - Especially for problems with a rather low number of cities
- How many iterations are needed to achieve a good result for a given problem is difficult to estimate
- Therefore, a predefined number of iterations yields unnecessary long computation times that do not improve the results
- One solution is to stop the algorithm, if the current solution(s) do not improve

# Metabirds

- How do you choose hyperparameters like move probabilities or small bird ratio?
- Apply an optimization algorithm to find optimal values
- What optimization algorithm? Artificial Feeding Birds!
- A Metabird's position is a value for all probabilities, ratios, etc.
  - Flying generates a random position in the hyperparameter space
  - Walking adds or subtracts a random delta from each parameter
  - Calculating the fitness of a Metabird
    - A TSP solver is instantiated with the hyperparameters of the Metabird
    - Multiple runs solving a TSP are averaged to assess the performance with the current parameters.
